

## BACKGROUND OF THE INVENTION

### 1. FIELD OF INVENTION

This invention relates in general to micro-actuators and, more particularly, to a bistable switch at least partially constructed of shape memory alloy (SMA).

### 2. DESCRIPTION OF THE RELATED ART

The first electro-mechanical and solid state micro-switches were developed in the late 1940's. The importance of micro-switch technology has increased as the trend toward miniaturization of electrical components developed. Current electro-mechanical micro-switches are expensive and complex to construct. Moreover, the components of current electro-mechanical micro-switches tend to be susceptible to mechanical breakdown. Solid state micro-switches are characterized by high on-state resistance, and, for many applications, undesirably high on-state "contact" coupling capacitance.

Another trend in the area of electronic switches has been to utilize SMA's to perform switching functions. A SMA material is a specialized alloy that exhibits a given mechanical movement in response to heating above a threshold temperature. The movement is relatively precise, predictable, and repeatable. When the SMA material is allowed to cool below the threshold temperature, it attains a ductile state. The SMA material is chiefly characterized by this ability to undergo reversible transformations between a first conformation at a sub-threshold temperature and a second conformation at a temperature above the threshold.

1 U.S. Patent No. 4,887,430 to Kroll et al. describes a bistable shape memory alloy  
2 (SMA) actuator having separate first and second SMA elements that move an actuator  
3 along a travel stroke between first and second positions. The Kroll actuator selectively  
4 heats the first and second SMA elements to move the actuator between the first and  
5 second positions. The actuator employs a mechanical frictional retainer to bias the  
6 actuator in its first and second positions.

7 The Kroll invention can be utilized to provide bistable mechanical actuation.  
8 However, the means for biasing the transducer or actuator in its first and second positions  
9 is mechanically separate and distinct from the element being actuated. Additionally, the  
10 Kroll actuator employs two or more separate SMA wires to provide movement between  
11 the first and second positions. Consequently, the Kroll device is not well suited for  
12 micro-switch designs that require the minimum number of components.

13 What is needed is a bistable SMA switch that is suitable for use as a micro-switch  
14 that is inexpensively manufacturable.

## 16 SUMMARY OF THE INVENTION

17 The present invention provides a SMA switch for use as a micro-switch. It has  
18 many aspects, as described herein. According to one aspect of the present invention, a  
19 SMA switch includes electrically conductive contact arms in sliding contact with a cursor  
20 that reciprocates between first and second positions to respectively trigger closed and  
21 open states of the switch. The cursor is moved between its first and second positions by a  
22 single continuous SMA element. In one embodiment the cursor includes a projection

1 which interacts with one of the contact arms to maintain the cursor in the first position to  
2 thereby maintain the closed state of the switch.

3 The single continuous SMA element can be a wire constructed of an alloy such as  
4 nitinol attached to a substrate at two different positions. The SMA element has first and  
5 second segments that are capable of being heated separately. In a preferred embodiment  
6 a first circuit heats the first segment when it conducts current and a second circuit heats  
7 the second segment when it conducts current. When the first segment is heated above a  
8 predetermined transition temperature and the second segment is maintained below the  
9 transition temperature, the first segment contracts to place the SMA element in a first  
10 conformation. When the second segment is heated above the transition temperature  
11 while the first segment is maintained below the transition temperature, the second  
12 segment contracts to place the SMA element into a second conformation.

13 The cursor is mechanically coupled to the SMA element between the SMA  
14 element's first and second segments. As the SMA element moves from its first to its  
15 second conformation, the cursor moves from its first to its second position. This  
16 movement of the cursor from its first to its second position causes a first contact arm to  
17 move to open the SMA switch.

18 In one embodiment, the bistable SMA switch includes a second electrically  
19 conductive contact arm disposed in sliding contact with a second surface of the cursor  
20 that is opposite a first surface of the cursor contacting the first contact arm. In this  
21 embodiment, the cursor includes a short bar that extends from the first surface to the  
22 second surface of the cursor. When the cursor is in its first position, the first and second  
23 contact arms are electrically coupled via the short bar to close the SMA switch. The

1 short bar has contact points that are recessed so that the contact arms are able to secure  
2 the cursor in its first position to maintain the closed state of the switch.

3 In a preferred embodiment, the first and second contact arms are both located on  
4 the same side of the cursor. The first contact arm is located within the travel path of the  
5 cursor as it travels from its second position to its first position so that the first contact arm  
6 is moved into direct contact with the second contact arm to close the switch. In a  
7 preferred embodiment the second contact arm is biased to exert a force on the first  
8 contact arm. The first contact arm transmits the force to the cursor. When the cursor is  
9 in the first position, this force maintains the cursor in its first position to maintain the  
10 closed state of the switch. This force must be overcome to move the cursor projection  
11 past the first contact arm (thereby displacing the first contact arm and the second contact  
12 arm) as the cursor moves from the first to the second position.

13 The first and second circuits that selectively heat the first and second segments of  
14 the SMA element share a common ground electrically coupled to the substrate. In a  
15 preferred embodiment, the ground includes a spring element that provides flexibility to  
16 permit the SMA element to alternate between the first and second conformations while  
17 maintaining electrical contact between the ground and the SMA element. In an  
18 alternative embodiment, the common ground includes a brush element that is in sliding  
19 contact with a fixed ground element attached to a mounting surface. The brush element  
20 is electrically coupled to the SMA element to enable the SMA element to alternate  
21 between its first and second conformations while maintaining electrical contact between  
22 the SMA element and the fixed ground element. In another embodiment the ground

comprises a wire bond electrically connecting the SMA element to the mounting surface via the cursor.

The cursor is preferably constructed of a combination metal and plastic and the first and second contact arms are preferably constructed by a machine stamping or an etching process.

### 7 DETAILED DESCRIPTION OF THE INVENTION

8 The present invention employs the unique properties of a shape memory alloy  
9 ("SMA") together with recent advances in micro-machining and etching to develop an  
10 efficient, effective and highly reliable micro-switch. The use of an SMA element in  
11 micro-switches increases the performance of switches or relays by several orders of  
12 magnitude. This increase in performance is accomplished because both stress and strain  
13 of the shape memory alloy can be very large, providing substantial work output per unit  
14 volume. Micro-mechanical switches using an SMA element as the actuation mechanism  
15 can exert stresses of hundreds of megapascals, tolerate strains of more than four percent  
16 and can work at common TTL voltages that are much lower than electrostatic or PZO  
17 requirements. Moreover, these SMA micro-switches can survive millions of cycles  
18 without fatigue.

19 SMA materials undergo a temperature related phase change when they reach  
20 temperatures above a threshold or transition temperature. The SMA material possesses a  
21 particular structure at a temperature below the transition temperature. When the  
22 temperature of the SMA material increases above the transition temperature, the structure  
23 of the SMA material is altered. If the SMA material has a wire shape, as the SMA wire

1 exceeds the transition temperature, the wire contracts to a known and reproducible extent.  
2 It is this property of SMA materials that is utilized to perform the switching functions of  
3 the present invention.

4 According to one of its aspects, the present invention employs a single continuous  
5 SMA wire to provide bidirectional mechanical forces for performing switching functions.  
6 Furthermore, contact arms that may be part of the circuit that the switch controls provide  
7 mechanical forces to maintain the SMA switch of the present invention in its closed state.  
8 Those features facilitate the incorporation of SMA material into micro-switches by  
9 reducing the number of mechanical and electrical components required to operate an  
10 SMA micro-switch.

11 Turning now to the drawings, Fig. 1 illustrates a thermally-actuated bistable SMA  
12 micro-switch 10 in accordance with one embodiment of the present invention. The  
13 micro-switch includes a single continuous SMA element that is preferably constructed of  
14 nitinol wire 11. Nitinol is an alloy of nickel and titanium. Substitutes for nitinol are  
15 well-known in the art. The nitinol wire 11 is secured to a substrate 13 at first and second  
16 attachment points 14 and 16. The substrate is constructed of an electrically conductive  
17 material and provides the points of attachment for the endpoints of the nitinol wire 11.  
18 The substrate can be mounted onto a printed circuit board, a flat plate of a ceramic  
19 material such as high density alumina ( $\text{Al}_2\text{O}_3$ ) or beryllia ( $\text{BeO}$ ), a glassy material such as  
20 fused silica, or any other material that can act as a support for the inventive switch  
21 structure.

22 The nitinol wire 11 can be attached at points 14 and 16 by crimping or other  
23 suitable means. By securing the nitinol wire to the substrate and selectively heating

1 segments of the nitinol wire 11, the conformation of the nitinol wire is selectively altered.  
2 Referring to Figures 1 and 5, a means for selectively heating first and second segments 68  
3 and 70 of the nitinol wire 11 is provided by first and second circuits 72 and 74. The first  
4 and second circuits share a common ground 38. A first switch 62 opens and closes the  
5 first circuit and a second switch 64 opens and closes the second circuit. In the operation  
6 of the bistable SMA micro-switch 10, the first and second switches 62 and 64 are  
7 coordinated so that if the first switch is closed, the second switch is opened and if the  
8 second switch is closed, the first switch is opened. When the first circuit 72 is closed, the  
9 first segment 68 of the nitinol wire 11 conducts current and, as a result, is heated above  
10 its transition temperature. Consequently, the first segment 68 contracts to place the  
11 nitinol wire 11 in its first conformation. The contraction of the nitinol wire requires a  
12 means, discussed in detail below, for maintaining electrical contact between the nitinol  
13 wire 11 and the ground 38 while permitting movement of the nitinol wire. When the  
14 second circuit 74 is closed, current runs through the second segment 70 of the nitinol wire  
15 thereby causing the second segment to contract to place the nitinol wire into its second  
16 conformation. The first and second segments of nitinol wire 11 could be replaced with  
17 two separate nitinol wires, according to some embodiments of the invention. The nitinol  
18 wire, in combination with the first and second circuits 68 and 70, functions as a  
19 transducer converting electrical energy into mechanical energy.

20 In a preferred embodiment, the means for maintaining electrical contact between  
21 the nitinol wire 11 and the common ground 38 is provided by a spring element 36 that  
22 extends to a ground attachment point 34 for the nitinol wire 11. The spring element 36 is  
23 flexible to permit the nitinol wire to alternate between its first and second conformations

1 while maintaining the connection between ground attachment point 34 and common  
2 ground 38. A cursor 12 is connected to the nitinol wire 11 so that, as the nitinol wire  
3 alternates between its first and second conformations, the cursor 12 is moved back and  
4 forth along its longitudinal axis. When the nitinol wire 11 is in its second conformation  
5 as shown in Fig. 1, the cursor 12 is in its second position. When the first circuit 72 closes  
6 causing the first segment 68 to contract so that the nitinol wire to moves into its first  
7 conformation, the cursor 12 is moved into its first position (not shown).

8 The cursor 12 may include a first short bar 40 and a second short bar 42 that are  
9 both made of an electrically conductive material. Although the cursor of Fig. 1 is shown  
10 as having two short bars, it can have fewer or more than two. The SMA micro-switch  
11 further includes two opposing sets of electrically conductive contact arms: first and  
12 second contact arms 18 and 20, and third and fourth contact arms 22 and 24. The contact  
13 arms are fastened to the mounting surface by soldering or some other well known means.  
14 When the cursor is in its second position as shown in Fig. 1, the SMA micro-switch is  
15 open because the contact arms are uncoupled from their respective short bars. When the  
16 cursor 12 is moved into its first position, the first and second contact arms 18 and 20 are  
17 electrically coupled via the first short bar 40 and the third and fourth contact arms 22 and  
18 24 are electrically coupled via the second short bar 42. The contact arms each are  
19 connected to electrical pads (not shown) on the mounting surface. When the cursor is in  
20 its first position and the opposing contact arms are electrically coupled via their  
21 respective short bars, the SMA micro-switch 10 is in its closed state. That is, current may  
22 flow from contact arm 18 to contact arm 20 through short bar 40, and similarly current  
23 may flow from contact arm 22 to contact arm 24 through short bar 42.

1           The first short bar 40 includes first and second contact points 26 and 28 and the  
2 second short bar 42 includes third and fourth contact points 30 and 32. In a preferred  
3 embodiment, the contact points are recessed with respect to the surface of the cursor so  
4 that, when the contact arms are coupled with their respective contact points, the contact  
5 arms secure the cursor 12 in its first position to maintain the SMA micro-switch 10 in its  
6 closed state.

7           Referring to Fig. 2, in another embodiment of the SMA micro-switch 10, the  
8 lateral surfaces of the cursor 12 do not include short bars to electrically couple the first  
9 and second contact arms 18 and 20 to each other and to contact the third and fourth  
10 contact arms 22 and 24 to each other. Instead, the first and third contact arms 18 and 22  
11 are located within the travel path of the cursor 12 as it moves from its second to its first  
12 position. The cursor 12 is tapered at its left end so that, when it is in its second position,  
13 the cursor does not contact the first 18 or third 22 contact arm. However, as the cursor  
14 12 moves from its second position to its first position, the cursor's first and second  
15 beveled surfaces 44 and 46 come into contact with extensions 48 and 50 that project  
16 respectively from first and third contact arms 18 and 22 toward the cursor 12. As the  
17 cursor continues toward its first position, the beveled surfaces 44 and 46 push the first  
18 and third contact arms 18 and 22 respectively into contact with the second and fourth  
19 contact arms 20 and 24. When the cursor 12 arrives at its first position, the extensions 48  
20 and 50 projecting from first and third contact arms 18 and 22 come to rest on the slightly  
21 tapered surface of the cursor to the right of the beveled surfaces 44 and 46, where they  
22 are held in place by friction and mechanical force.

1 In a preferred embodiment, the lateral surfaces of the cursor 12 include first and  
2 second projections 45 and 47. The projections provide an obstacle against the movement  
3 of the cursor from its first to its second position. The second and fourth contact arms 20  
4 and 24 preferably exert forces respectively through first and third contact arms 18 and 22  
5 urging the first and third contact arms against the lateral surfaces of the cursor. Sufficient  
6 force must be generated by the first segment 68 of the nitinol wire 11 to overcome the  
7 biases of the second and fourth contact arms 20 and 24 to enable the projections 45 and  
8 47 to pass by the first and second contact arm extension 48 and 50.

9 When the cursor 12 is in its first position, the first contact arm 18 is forced into  
10 abutment with the second contact arm 20 and the third contact arm 22 is forced into  
11 abutment with the fourth contact arm 24. Although not shown in Fig. 2, the contact arms  
12 18, 20, 22, 24 are electrically coupled to leads on the mounting surface. When the cursor  
13 is in its first position and the first and second contact arms 18 and 20 are coupled and the  
14 third and fourth contact arms 22 and 24 are coupled, the SMA micro-switch is closed and  
15 current flows through the electrically coupled contact arms. When the cursor 12 reverts  
16 back to its second position, the contact arms uncouple and the SMA micro-switch 10  
17 opens.

18 Instead of a spring element 36, an alternative embodiment utilizes a brush element  
19 54 connected to the cursor 12 to maintains sliding contact with the common ground 38 as  
20 the cursor alternates between its first and second positions. Alternative embodiments will  
21 be apparent that also allow a dynamic contact between the nitinol wire 11 and common  
22 ground node 38 using sliding elements or other assemblies. The two different  
23 embodiments of the means for maintaining contact between the nitinol wire 11 and the

1 common ground 38 can be utilized interchangeably with either the cursor/contact arm  
2 assembly of Fig. 1, Fig. 2 or Fig. 4. Fig. 3 shows a preferred embodiment wherein the  
3 cursor/contact arm assembly of Fig. 2 is combined with the spring element 36 of Fig. 1.  
4 An alternative embodiment of the common ground node provides a wire bonded from the  
5 mounting surface to the nitinol wire via the cursor.

6 Fig. 4 illustrates another alternative embodiment that employs a two-headed  
7 cursor 12. A first head 90 has two projections 94 and 96 on its lateral surfaces that  
8 function to maintain the cursor in its first position. A second head 92 also has two  
9 projections 98 and 100 to help maintain the closed state of the switch by maintaining the  
10 cursor 12 in its first position. In this alternative embodiment, the portions of the first and  
11 second heads 90 and 92 (in contact with the first 18, second 20, third 22 and fourth 24  
12 contact arms) are made of a conductive material. The cursor in Fig. 4 is shown in its  
13 second position so that the switch is open. When the cursor moves into its first position,  
14 first and second contact arms become electrically coupled via the first cursor head 90 and  
15 the third and fourth contact arms become electrically coupled via the second cursor head  
16 92.

17 Referring to Figs. 6 and 7, in one embodiment, the SMA element 11 is fixedly  
18 secured at the first point of attachment 14 utilizing a machine stamping technique. The  
19 material to which the SMA element is secured is an electrically conductive material 76  
20 constructed, for example, of a suitable metal. The machine stamping technique punctures  
21 the conductive material to create flaps 72 and 74. The two flaps have three edges created  
22 by the machine stamping process. By bending the flaps 72 and 74 out of the plane of the  
23 conductive material, a space is created in which the SMA element can be inserted. Figs.

6 and 7 show the space created by bending the flaps in this manner. By bending the ends of the flaps back toward the plane of the conductive material after the SMA element has been inserted into the space, the SMA element is fixedly secured at the first attachment point 14. Other means of securing can include welding or soldering.

One concern addressed by the present invention is the need to control the motion of the cursor 12 so that the contact arms are maintained within the same plane with the cursor as the cursor moves between its first and second positions. In a preferred embodiment, a half-etching technique is utilized to construct the contact arms and the cursor to maintain co-planarity between the contact arms and the cursor during operation of the switch 10. Fig. 9 shows a cross section of the switch 10 taken along line A--A in Fig. 8. Fig. 10 shows a cross section taken along line B--B in Fig. 8. As shown in Fig. 9, a first region of the cursor 12 is half-etched from top. The top surface of the cursor is etched away along its outside edges to create grooves along the two outside lateral edges of the length of the cursor 12. The contact arms are half-etched from the bottom to form grooves along the length of the contact arms 18 and 22. These grooves along the bottom lengths of the contact arms 18 and 22 are complementary to the grooves along the lateral edges of the length of the cursor. When the contact arms are fixedly secured into the position shown in Fig. 9, the contact arms prevent the cursor from moving in an upward direction while the cursor moves along its long axis.

As shown in Fig. 10, the half-etching patterns of the cursor and the contact arms at the plane intersected by line B--B differ from the half-etching patterns shown in Fig. 9. The outside edges along the length of the cursor are half-etched from the bottom. The contact arms are half-etched from the top. When assembled as in Fig. 10, the grooves

1 along the length of the outside edge of the cursor interlock with the grooves along the top  
2 length of the first and third contact arms 18 and 22. This interlocking allows the cursor to  
3 move along its long axis while restricting its downward movement.

4 The interlocking between the cursor 12 and the first and third contact arms 18 and  
5 22 shown in Fig. 9 restricts upward movement of the cursor while the interlocking  
6 between the cursor and the contact arms shown in Fig. 10 restricts the downward  
7 movement of the cursor. This complementary half-etching pattern of the cursor and  
8 contact arms maintains co-planarity between the cursor and contact arms while the cursor  
9 moves along its long axis between its first and second positions.

10 Figs. 11 and 12 illustrate another embodiment of the switch 10. In this  
11 embodiment of the switch, the first and second short bars 40 and 42 extend out from the  
12 cursor 12. The orientation of the short bars is co-planar with respect to the remaining  
13 portion of the cursor. A first insulator 78 made of an electrically insulating material is  
14 attached to the upper surface of the first short bar and a second insulator 80 is attached to  
15 the upper surface of the second short bar. The insulators can be located on either the  
16 upper or lower surfaces or both surfaces of the short bars. The contact arms in this  
17 embodiment are in sliding contact with the top and bottom surface short bars 40 and 42 of  
18 the cursor 12. Specifically, the first and second contact arms 18 and 20 are respectively  
19 in sliding contact with the top and bottom surface of the first short bar 40 and the third  
20 and fourth contact arms 22 and 24 are respectively in sliding contact with the top and  
21 bottom surfaces of the second short bar 42.

22 The opposing forces exerted on the first contact bar 40 by the first and second  
23 contact arms 18 and 20 and the opposing forces exerted on the second contact bar by the

1 third and fourth contact arms restrict the upward and downward movement of the cursor.  
2 When the cursor is positioned so that the contact arms are in direct contact with the short  
3 bars, the switch is closed. When the cursor is positioned so that the first insulator 78  
4 contacts the first contact arm 18 and the second insulator 80 contacts the fourth contact  
5 arm 24, the switch is open.

6 One of the prime benefits of the invention disclosed herein is the simplicity of its  
7 manufacture. For example, the conductive metal elements may be made by a simple  
8 stamping process, the cursor may be made of injection-molded plastic, and nitinol wire  
9 11 may be made of a single piece of wire.

10 The foregoing description of particular embodiments does not limit the scope of  
11 the invention, as defined by the claims that follow. Those skilled in the art will recognize  
12 that there are many alternative embodiments that use the inventive ideas of the present  
13 invention without adopting the details of implementation disclosed herein.

14 Although the actuator of the present invention has been described in the concept  
15 of an electrical switch, those skilled in the art will recognize that aspects of the invention  
16 are equally applicable to other mechanical actuators, such as those for opening and  
17 closing valves, tilting mirrors, etc.
